SHIT...
OR NET OF A MILLION SPIES
Overflows & Format Strings
Announcements...

• Homework 1 due in ~1 week
• Project 1 release Real Soon Now:
  • Practical exploitation of vulnerable SUID programs running in a VM
  • Have you done Project 0?
Internet of Shit...

- A device produced by the lowest bidder...
  - That you then connect through the network
- This has a very wide *attack surface*
  - Methods where an attacker might access a vulnerability
- And its often incredibly *cost sensitive*
  - Very little support after purchase
    - So things don't get patched
  - No way for the user to tell what is "secure" or "not"
    - But they can tell what is cheaper!
    - And often it is *insanely* insecure:
      Default passwords on telnet of admin/admin...
      Trivial buffer overflows
Net Of A Million Spies...

- Device only communicates through a central service
  - Greatly reduces the attack surface but...
- Most of the companies running the service are "Data Asset" companies
  - Make their money from advertising, not the product themselves
    - May actually subsidize the product considerably
  - Some you know about: Google, Amazon
  - Some you may not: Salesforce
- Only exception of note is Apple:
  - I may talk about HomeKit later...
    But you still have to trust that the HomeKit product doesn't report to a third party.
Traveler Information

Traveler 1 - Adults (age 18 to 64)

To comply with the TSA Secure Flight program, the traveler information listed here must exactly match the information on the government-issued photo ID that the traveler presents at the airport.

Title (optional): Dr.  First Name: Alice  Middle Name:  Last Name: Smith
Gender: Female  Date of Birth: 01/24/93

Travelers are required to enter a middle name/initial if one is listed on their government-issued photo ID. Some younger travelers are not required to present an ID when traveling within the U.S. Learn more

Known Traveler Number/Pass ID (optional): 
Redress Number (optional):

IE's Role in the Google-China War

By Richard Adhikari
TechNewsWorld
01/15/10 12:25 PM PT

The hack attack on Google that set off the company’s ongoing standoff with China appears to have come through a zero-day flaw in Microsoft’s Internet Explorer browser. Microsoft has released a security advisory, and researchers are hard at work studying the exploit. The attack appears to consist of several files, each a different piece of malware.

Computer security companies are scurrying to cope with the fallout from the Internet Explorer (IE) flaw that led to cyberattacks on Google (Nasdaq: GOOG) and its corporate and individual customers.

The zero-day attack that exploited IE is part of a lethal cocktail of malware that is keeping researchers very busy.

"We’re discovering things on an up-to-the-minute basis, and we’ve seen about a dozen files dropped on infected PCs so far," Dmitri Alperovitch, vice president of research at McAfee Labs, told TechNewsWorld.

The attacks on Google, which appeared to originate in China, have sparked a feud between the Internet giant and the nation’s government over censorship, and it could result in Google pulling away from its business dealings in the country.

Pointing to the Flaw

The vulnerability in IE is an invalid pointer reference, Microsoft (Nasdaq: MSFT) said in security advisory 979352, which it issued on Thursday. Under certain conditions, the invalid pointer can be accessed after an object is deleted, the advisory states. In specially crafted attacks, like the ones launched against Google and its customers, IE can allow remote execution of code when the flaw is exploited.
Disclaimer: x86-32

- For this class, we are going to use 32b x86...
  - Why?

- It is both common and weak...
  - Almost everyone in this class has access to an x86 system: Mac, Linux, Windows...
    And can run a 32b x86 virtual machine
  - 64b x86 systems generally include a lot better "mitigations": System defenses designed to limit exploitation in this manner

- But these attacks do apply to other microarchitectures
  - Phones are 64b ARM: Can still be exploited in this manner
  - The Internet of Things is mostly 32b or 64b ARM...
    and often neglects to include the mitigations!
x86 vs RISC-V

• All RISC architectures are the same except for one or two ‘seems like a good idea at the time’ design decisions … But x86 is a very different beast from a programming viewpoint

• RISC-V: 32 general purpose registers (well, 31 + x0…)
  • All operations are on data in registers apart from loads & stores

• x86: only a few registers
  • Operations can be directly on data in memory, including a large number relative to the stack
  • EG, add takes two operands, adds them together, and stores the result in the first
    • The first can be a register or memory location
    • The second can be a register, a memory location, or an immediate…
      • But the first and second can’t both be a memory location?!!
The main x86 registers…

• General purpose: EAX-EDX
  • What you use for computing and other stuff, sorta…

• Indexes & Pointers
  • EBP: “Frame pointer”: points to the start of the current call frame on the stack
  • ESP: “Stack pointer”: points to the current stack
    • PUSH and POP
      • Decrement the stack pointer and store something there
      • Load something and increment the stack pointer
    • Most operations are done with data on the stack…
Linux (32-bit) process memory layout

Reserved for Kernel

user stack

shared libraries

run time heap

static data segment

text segment (program)

unused

$esp

brk

Loaded from exec
x86 function calling

- Place the arguments on the stack
  - Compare with RISC-V where the first arguments are in registers
- CALL the function
  - Which pushes the return address onto the stack (RIP == Return Instruction Pointer)
- do your stuff…
  - Start by saving the old EP on the stack (SFP == Saved Frame Pointer)
- Restore everything
  - Reload EBP, pop ESP as necessary
- RET
  - Which jumps to the return address that is currently pointed to by ESP
  - And can optionally pop the stack a lot further…
user stack
shared libraries
run time heap
static data segment
text segment (program)
unused

arguments
return address
stack frame pointer
exception handlers
local variables
callee saved registers

To previous stack frame pointer
To the point at which this function was called
void safe() {
    char buf[64];
    ...
    fgets(buf, 64, stdin);
    ...
}
void safer() {
    char buf[64];
    ...
    fgets(buf,sizeof(buf),stdin);
    ...
}
Assume these are both under the control of an attacker.

```c
void vulnerable(int len, char *data) {
    char buf[64];
    if (len > 64)
        return;
    memcpy(buf, data, len);
}
```

`memcpy(void *s1, const void *s2, size_t n);`

`size_t` is `unsigned`.

What happens if `len == -1`?
void safe(size_t len, char *data) {
    char buf[64];
    if (len > 64)
        return;
    memcpy(buf, data, len);
}
void f(size_t len, char *data) {
    char *buf = malloc(len+2);
    if (buf == NULL) return;
    memcpy(buf, data, len);
    buf[len] = '\n';
    buf[len+1] = '\0';
}

Vulnerable!
If \textit{len} = 0xffffffff, allocates only 1 byte

Broward Vote-Counting Blunder Changes Amendment Result

POSTED: 1:34 pm EST November 4, 2004

BROWARD COUNTY, Fla. -- The Broward County Elections Department has egg on its face today after a computer glitch misreported a key amendment race, according to WPLG-TV in Miami.

Amendment 4, which would allow Miami-Dade and Broward counties to hold a future election to decide if slot machines should be allowed at racetracks, was thought to be tied. But now that a computer glitch for machines counting absentee ballots has been exposed, it turns out the amendment passed.

"The software is not geared to count more than 32,000 votes in a precinct. So what happens when it gets to 32,000 is the software starts counting backward," said Broward County Mayor Ilene Lieberman.

That means that Amendment 4 passed in Broward County by more than 240,000 votes rather than the 166,000-vote margin reported Wednesday night. That increase changes the overall statewide results in what had been a neck-and-neck race, one for which recounts had been going on today. But with news of Broward’s error, it’s clear amendment 4 passed.
void vulnerable() {
    char buf[64];
    if (fgets(buf, 64, stdin) == NULL)
        return;
    printf(buf);
}
printf("you scored %d\n", score);
printf("you scored \n", score);

score
0x8048464
rip
printf()
sfp

0x8048464
printf("a %s costs $%d\n", item, price);
`printf("a \% costs $%n", item, price);

price

item

0x8048464

rip

printf();

sfp

\0 \n d %
$ s t
$ o c
s % a

0x8048464`
Fun With **printf** format strings...

```c
printf("100% dude!");  // Format argument is missing!
```
```c
printf("100% dude!");
```
More Fun With `printf` format strings...

```c
printf("100% dude! ");
⇒ prints value 4 bytes above retaddr as integer
printf("100% sir! ");
⇒ prints bytes pointed to by that stack entry
   up through first NUL
printf("%d %d %d %d ... ");
⇒ prints series of stack entries as integers
printf("%d %s ");
⇒ prints value 4 bytes above retaddr plus bytes
   pointed to by preceding stack entry
printf("100% nuke’m! ");
```

What does the `%n` format do??
int report_cost(int item_num, int price) {
    int colon_offset;
    printf("item %d:%n $%d\n", item_num, &colon_offset, price);
    return colon_offset;
}

report_cost(3, 22) prints "item 3: $22"
    and returns the value 7

report_cost(987, 5) prints "item 987: $5"
    and returns the value 9

%n writes the number of characters printed so far into the corresponding format argument.
Fun With `printf` format strings...

```c
printf("100% dude! ");
⇒ prints value 4 bytes above retaddr as integer
printf("100% sir! ");
⇒ prints bytes pointed to by that stack entry
    up through first NUL
printf("%d %d %d %d...");
⇒ prints series of stack entries as integers
printf("%d %s");
⇒ prints value 4 bytes above retaddr plus bytes
    pointed to by preceding stack entry
printf("100% nuke'm!");
⇒ writes the value 3 to the address pointed to by stack entry
```
void safe() {
    char buf[64];
    if (fgets(buf, 64, stdin) == NULL) {
        return;
    }
    printf("%s", buf);
}
